Foundations Of Programming: Python
Assignment_05

Introduction

This week's module has been a continuation of the last module where we explored writing data to files and Multidimensional data constructs. We will be working with files\lists and using dictionaries instead of lists for the rows.

LAB 05-A: Working with Files and Lists

Lists can contain other lists as elements. A typical use of such nested (or multidimensional) lists is to represent tables of values consisting of information arranged in rows and columns.

Python supports file handling and allows users to handle files i.e., to read and write files, along with many other file handling options, to operate on files. Here, we create two-dimensional lists to read and write data from list to file.

Completed the starter code to read and write data from list to file and Compiled to verify output:

LAB 05-B: Working with List of Dictionaries

Dictionary is like any element in a list. Therefore, you can access each dictionary of the list using index. A Python list is an ordered sequence of objects, whereas dictionaries are unordered. They are similar to sequence types but replace the index and storing in sequence by storing key: value pairs. This means instead of the index, the programmer defines a key under which the values are being stored and accessed. Dictionaries use the braces {} operator. The full syntax is {key: value}. Key:Value pairs are separated by commas.

Dictionary keys are a lot like named columns in a spread sheet or database, and the dictionary is a row of data. Like creating a list of lists to form a 2D list to resemble a 2D table, dictionaries can be inserted into lists to create a list of dictionaries 2D table.

```
72
73     elif strChoice == 'd':
74         entry_Del = int(input('Enter the ID of the entry you want to delete: '))
75
76         for row in tblDict:
77             if entry_Del == row['CD ID']:
78                 tblDict.remove(rowDict)
79         pass
80
81     elif strChoice == 's':
82         # 4. Save the data to a text file CDInventory.txt if the user chooses so
83         objFile=open(strFileName,'w')
84         for row in tblDict:
85             strRow=''
86             for item in row.values():
87                 strRow=strRow+str(item)+','
88             strRow=strRow[:-1]+'\\n'
89             objFile.write(strRow)
90         objFile.close()
91         print('CD inventory saved to file.\\n')
92     pass
93
```

Figure 6 - Screen capture of Lab05-B showing deletion of entry\\save the data to text file

Modified the code from Lab 05-A to use dictionaries instead of lists for the rows. Compiled to verify output:

Summary

In this assignment\module, we continued with lists, covered Dictionaries and file read / write access. We created a script template and looked at ways to improve our scripts. We got a brief introduction to what git and GitHub are and created a first repository. We used Spyder as our IDE.
